

THE IDENTIFICATION AND CONTROL OF DIPTERA PEST SPECIES ON WHEAT CROPS

Dana Malschi¹⁾

ABSTRACT

The group of *Diptera* may be considered important within the structure of pests existing in wheat crops in Romania. In the last years, the increase of damages produced by *Diptera* larvae was registered at the crops intensely affected by climatic unfavourable conditions (excessive drought, low temperatures) and by the exploitation system with incomplete or incorrect crop technologies. The present work offers an ensemble of knowledge necessary to the species identification by the correlation of morphological, ecological, habitat and geographical criteria, for a real pointed out of the importance and for the forecast of losses.

Key words: *Opomyzidae, Anthomyiidae, Chloropidae, Cecidomyiidae*; distribution in Romania; morphology; life-cycle, and control in Transylvania.

INTRODUCTION

The described main *Diptera* species are on their geographical area and perform a considerable high biological reserves and attack possibilities on winter wheat crops. The ecological factors and agrotechnical methods determined the distribution range, the composition of species and the economic importance of the attack in different cereal areas of the country. So, the early emergence of crops in September provided the dangerous manifestation of attack of frit fly (*Oscinella frit* L.), hessian fly (*Mayeriola destructor* Say.) and black fly (*Phobia securia* Tiensuu). The biological potential and attack produced on the spring by yellow small fly (*Opomyza florula* F.) and wheat bulb fly (*Delia coarctata* Fl.) are increasing when the emergence of wheat is achieved in October. The late emergence of crops in November, provided the preferential attack of black flies (*Phobia penicillifera* Jermy and *Ph. securis*) and the development of species populations, especially in Transylvania, Moldova and Oltenia (Alessandri, 1945; Bărbulescu et al., 1973; Mustea et al., 1982; Malschi, 1993).

In the cereal areas with an important biological reserves of *Diptera* pests, the following integrated plant protection preventive measures are suitable to forecast: the late

sowing date (in the first half of October); adequate technological measures providing for a good development of plants; cultivation of wheat hardy varieties with productive tillering compensatory capacity after the attack; the seed treatment with insecticides. Some special experimental insecticide treatments applied in autumn had an important effect on the yields increase of 15-32 %, using dimethoate, trichlorphon or dimethoate with deltametrin. At the early spring the effect of insecticides applied in the early and in the late emergent wheat crops was significantly on the increasing yields with 9-15% when dimethoate, trichlorphon or carbaril, or dimethoate with deltametrin or with methylpirimiphos were used (Malschi and Mustea, 1996).

MATERIALS AND METHODS

The paper presents data concerning the structure of *Diptera* species attacking wheat crops in autumn and in spring during 1978-1985 and the distribution maps of the main species in Romania. This study was made by author with the cooperation of Plant Protection County Centers, Central Laboratory of Phytosanitary Quarantine - Bucharest and Research Institute for Cereals and Industrial Crops - Fundulea, for the samples gathering.

The data related to the composition of species, biology and experimental control of phytophagous flies were studied from 1980 to 1997 at the Agricultural Research Station Turda.

RESULTS ON THE STUDY OF SPECIES STRUCTURE AND ABUNDANCE

Sweep net catches of adults and larval instar examinations of tillers attacked (the dead – heart tillers) proved the presence of different species. Considering their structural

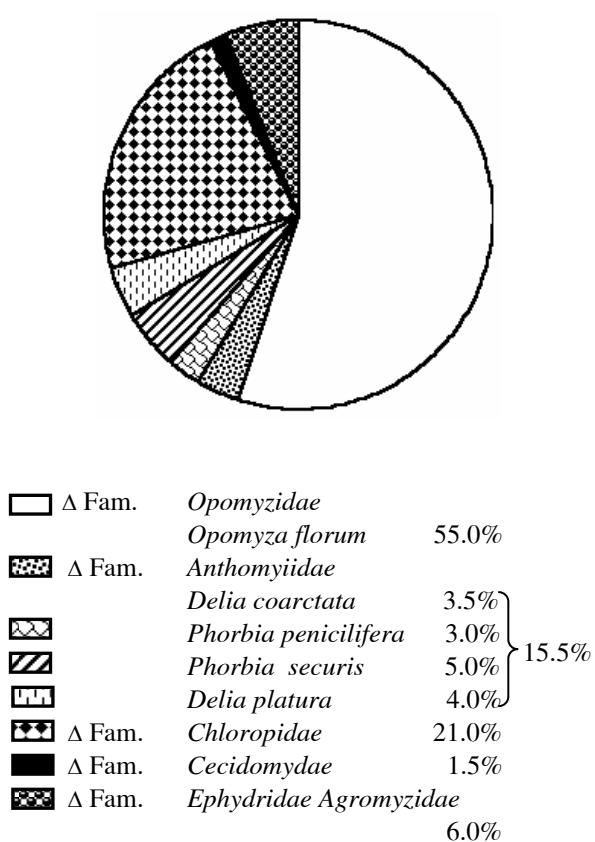

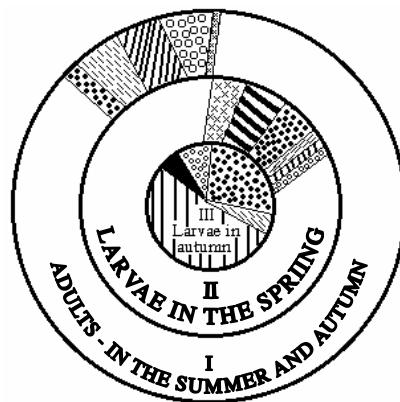

Figure 1. The structure of *Diptera* species attacking wheat crops in Romania during 1978-1985

dominance and the losses produced, the most important species belonged to the families: *Opomyzidae*, *Anthomyiidae*, *Chloropidae* and *Cecidomyidae* (Figure 1).

Autumn infestation was mainly caused by *Oscinela frit*, *Phorbia securis*, *Delia platura* Mg., *Mayetiola destructor*. The most important attack was caused at the beginning of spring by *Opomyza florum*, *Delia coarctata*, *Phorbia penicillifera* and *Phorbia securis* (Figure 2).

EXPERIMENTAL CHEMICAL CONTROL MEASURES, INSECTICIDES EFFICIENCY

The variety of insecticidal products used in the cereal field crops was the support for the research on the efficiency of insecticides in order to control the main diptere species

Dominance structure	Percentage (%) in			Total number
	I May-Sept.	II April-May	III Oct.-Nov	
<i>Opomyza florum</i>	87.0	78.0	-	12723
<i>Delia coarctata</i>	0.3	5.0	-	341
<i>Delia platura</i>	3.3	0.5	2.0	365
<i>Phorbia penicillifera</i>	-	5.0	-	318
<i>Phorbia securis</i>	0.6	7.0	32.0	943
<i>Chloropidae</i>	4.3	2.0	54.0	1419
<i>Cecidomyidae</i>	-	0.5	7.0	135
<i>Ephydriidae Agromyzidae</i>	4.5	2.0	5.0	608
Total individual number	2315	5925	1612	16582
Total sample number	316	483	235	1075
Average damagees (% plants)	-	8.8	3.5	-

Figure 2. The dominance structure *Diptera* pests of wheat during 1978 – 1986, determined by the different periods of samples gathering: I – in May – November (adults); II – in April – May (larvae); III – in October – November (larvae)

under central Transylvania conditions. During 1981 to 1997 we tested the biological efficiency and selective moment of application for different insecticides: organophosphorus, organochlorous, carbamats, synthetic pyrethroids etc. The insecticide treatments could be applied in the spring at the moment of the maximum biological efficiency (Figures 3 and 4). That is at the Ith larval instar of *Opomyza florum* and *Delia coarctata* and simultaneously, at the adult flying of *Phorbia securis* and *Phorbia penicillifera*. At this special moment it is possible to achieve a partial larval mortality, about 50-75%, only (Table 1), because of the different species biological life-cycle and the feeding parasitical behaviours of larvae within the wheat tillers.

The preventive seed insecticide treatments had a partial efficiency on the control of *Diptera* pests too (Table 2).

CONCLUSIONS

The present study provided faunistic, biological and ecological data necessary to implement different possible measures in order to achieve a real integrated system for the control of the main *Diptera* species damaging winter wheat crops.

The integrated pest control system has to be a synthesis of means to use the bio-technological favourable factors, firstly, for the plant protection against *Diptera* pests of wheat: - optimum zonal agro-technological measures of wheat crops; wheat varieties with good compensatory capacity after the attack; preventive plant protection measures.

The special chemical control has to be related with the adequate economic damage thresholds, the knowledge on the side-effects of insecticides on the beneficial arthropod fauna, protection and use of auxiliary activity of entomophagous natural reservoir in cereal agroecosystems. The spring treatments for *Diptera* pest control are very difficult to applied at the optimal moment because of the agroecological zone conditions and because of the different *Diptera* species attacking on wheat crops. The average efficiency of treatments are only partial (50-75% larval mortality).
